## PROBLEM 15

### Answer:

1. Assume  $q$  is inside  $P$ . We want to find the closest point to  $q$  in  $\{p_1, \dots, p_n\}$ .

#### Reasoning:

Hard and required  $\Omega(n)$  runtime. Arrange all points on the circumference of a circle like regular convex  $n$ -polygon enclosing point  $q$  as its center. If the algorithm is deterministic and assumes an easy case, some points remain unvisited. For those unvisited point, we one of them closer. Therefore, the algorithm can not find the correct closest point and outputting incorrect results.

2. Assume  $q$  is outside  $P$ . We want to find the closest point to  $q$  in  $\{p_1, \dots, p_n\}$ .

#### Reasoning:

Hard and required  $\Omega(n)$  runtime. Place all points on a quarter-circle like regular convex  $n$ -polygon enclosing point  $q$  while ensuring  $P$  is convex and non-enclosing. Assume easy, then there will be some point that the algorithm (deterministic) will not visit. For an unvisited point, we move it closer. Therefore, the algorithm can not find the correct closest point and outputting incorrect results.

3. Assume  $q$  is inside  $P$ . We want to find the farthest point to  $q$  in  $\{p_1, \dots, p_n\}$ .

#### Reasoning:

Hard and required  $\Omega(n)$  runtime. Similar to Q1, but this time we move an unvisited point further.

4. Assume  $q$  is outside  $P$ . We want to find the farthest point to  $q$  in  $\{p_1, \dots, p_n\}$ .

#### Reasoning:

Hard and required  $\Omega(n)$  runtime. Similar to Q2, but this time we move an unvisited point further.

5. Assume  $q$  is inside  $P$ . We want to find the closest point to  $q$  on  $P$ .  
**Reasoning:**  
Hard and required  $\Omega(n)$  runtime. Similar to Q1 again, The number of edges equals the number of points, so we still need at least  $O(n)$  runtime.
6. Assume  $q$  is outside  $P$ . We want to find the closest point to  $q$  on  $P$ .  
**Reasoning:**  
Easy and can be solved within  $O(\log n)$ .
7. Assume  $q$  is inside  $P$ . We want to find the farthest point to  $q$  on  $P$ .  
**Reasoning:**  
Hard and required  $\Omega(n)$  runtime. Similar to Q3, so similar argument can be made.
8. Assume  $q$  is outside  $P$ . We want to find the farthest point to  $q$  on  $P$ .  
**Reasoning:**  
Hard and required  $\Omega(n)$  runtime. Similar to Q4. The farthest point must lie on the circumcircle as all other points are on an  $n$ -gon, so similar argument can be made.

## PROBLEM 16

*Proof.* Let  $\{P_1, \dots, P_n\}$  be the collection of points of a convex polygon  $P$ .

### Steps for Triangulation:

1. Order points in clock-wise order  $\{p_1, \dots, p_n\}$ .
2. Pick the **longest side** from **diagonal** or **side** of  $P$ :  $P_i, P_j$ .
3. Pick the third point  $P_k$  such that  $P_k$  is the neighbor of point  $p_i$  OR  $p_j$ . WLOG, pick the neighbor of  $p_i$  as the third point. We denote the third point as  $P_{i+1}$  or  $P_{j-1}$ . **Note:** This  $P_k$  is on the opposite arc from  $P_i P_j$ .
4. Form the first triangle as  $\triangle P_i P_j P_k$ :

- (a) Then we iteratively add the rest of the polygon of the “half” of the polygon as:

**Note:** The neighbor of  $P_{i+n}$  is  $P_{j-1}$  and  $P_{j-3}$ .

$$P_j P_{j+1} P_{j+2}, \dots, P_j P_{i+n} P_{j-1}$$

- (b) For the rest of the “half” of the polygon:

**Note:** The neighbor of  $P_{j+m}$  is  $P_{i-1}$  and  $P_{i-3}$ .

$$P_i P_j P_{j+1}, \dots, P_i P_{j+m} P_{i-1}.$$

□

## PROBLEM 17

The algorithm identifies all "good" points by first constructing the Voronoi diagram of the given points, which efficiently captures proximity relationships in  $O(n \log n)$  time. For each point  $p_i$ , it examines only its neighboring points in the Voronoi diagram, as these are the only ones that could potentially interfere with placing a new circle. By computing the angular intervals where a circle of radius  $\ell$  touching  $C_i$  would intersect any neighboring  $C_j$ , the algorithm determines the directions that are blocked. If there exists at least one direction where such interference does not occur, the point  $p_i$  is therefore "good".

```
# Helper Functions
def compute_interfering_angles(p_i, p_j, r, l, d_ij):
    # Calculate the angle between p_i and p_j
    delta_x = p_j.x - p_i.x
    delta_y = p_j.y - p_i.y
    alpha = atan2(delta_y, delta_x)

    # Law of Cosines to find the angular width
    cos_theta = (d_ij**2 + (r + l)**2 - (r + l)**2) / (2 * d_ij * (r + l))
    if abs(cos_theta) <= 1:
        theta = acos(cos_theta)
        # The interfering interval is [alpha - theta, alpha + theta]
        interval = [(alpha - theta) % (2 * pi), (alpha + theta) % (2 * pi)]
        # Handle interval wrapping around 2pi
        if interval[0] > interval[1]:
            return [(interval[0], 2 * pi), (0, interval[1])]
        else:
            return [interval]
    else:
        # Circles do not intersect; no interfering angles
        return []

# Main Function
def find_good_points(P, r, l):
    # Construct the Voronoi diagram
    # Need O(n log n)
    V = voronoi_diagram(P)

    good_points = []

    # For each point p_i
    # Need O(n)
    for p_i in P:
        interfering_angles = [] # List to store interfering angular intervals

        # Get neighboring points in the Voronoi diagram
```

```

neighbors = V.get_neighbors(p_i)

# For each neighbor p_j
for p_j in neighbors:
    d_ij = distance(p_i, p_j)

    # Only consider neighbors that may interfere
    if d_ij < 2 * (r + l):
        # Compute the angular intervals of interference
        angles = compute_interfering_angles(p_i, p_j, r, l, d_ij)
        interfering_angles.extend(angles)

# Compute the union of interfering intervals
interfering_union = union_of_intervals(interfering_angles)

# Determine the complement of the union over [0, 2pi)
non_interfering_angles = complement_of_intervals(interfering_union, 0, 2 * pi)

# If there is at least one non-interfering angle, p_i is good
if non_interfering_angles:
    good_points.append(p_i)

return good_points

```

## PROBLEM 18

Result:

Processing $n$	Max Depth	Avg Depth
10	8	5.45273631840796
20	12	7.750312109862672
30	18	8.939478067740144
40	17	9.610121836925961
50	21	9.93361327734453

Table 1: Depth statistics for different values of  $n$

### Short Analysis:

The result I got is reasonable, with the average depths increasing in  $\log n$  as expected, indicating that the algorithm effectively maintains a balanced DAG structure. Although the maximum depths are somewhat higher than theoretical predictions, they remain within an acceptable range considering the algorithm's randomness and the potential for local depth increases during edge legalization.

### Implementation:

The following code of randomized Delaunay triangulation algorithm with history DAG was implemented in Python:

# Data Structures Definitions

```
class Point:
    def __init__(self, x, y):
        self.x = x
        self.y = y
```

```

class SegmentWrapper:
    """
    Helper class to uniquely identify a segment irrespective of point order.
    """
    def __init__(self, p1, p2):
        # Ensure consistent ordering
        if (p1.x, p1.y) < (p2.x, p2.y):
            self.p1, self.p2 = p1, p2
        else:
            self.p1, self.p2 = p2, p1

    def __eq__(self, other):
        return (self.p1.x, self.p1.y) == (other.p1.x, other.p1.y) and \
            (self.p2.x, self.p2.y) == (other.p2.x, other.p2.y)

    def __hash__(self):
        return hash(((self.p1.x, self.p1.y), (self.p2.x, self.p2.y)))

    def __repr__(self):
        return f"Segment(({self.p1.x}, {self.p1.y}) - ({self.p2.x}, {self.p2.y}))"

class Triangle:
    def __init__(self, p1, p2, p3):
        self.vertices = [p1, p2, p3] # Points
        self.edges = [
            SegmentWrapper(p1, p2),
            SegmentWrapper(p2, p3),
            SegmentWrapper(p3, p1)
        ]
        self.neighbors = {} # edge -> adjacent triangle
        self.children = [] # For history DAG
